

The guardrail decision

Codeshare-rebooking agent. Answer: $4a = c$ (86%), $4b = f$ (no), $4c = h$ (50%), $4d = k$ (yes).

Teaching point. A bar comes from the cost of a mistake. A hold lowers the damage, which lowers the bar, which can make an already-built model shippable.

Before and after the hold

Same 82% model. The hold lowered the damage, the bar fell from 86% to 50%, and it became shippable.

$4a = c$ (86%) · $4b = f$ below the bar · $4c = h$ (50%) · $4d = k$ now it ships.

The arithmetic, shown

	Damage	Saving	Rights per wrong	Bar = $1 - 1/(n+1)$	82% vs bar
No hold	\$48	\$8	6	$85.7\% \approx 86\%$	below
With a hold	\$8	\$8	1	50%	clears

Why 80% ($4a-b$) is the tempting wrong answer. It is the flight agent's bar from the deck, where the damage was \$32. Learners recall it instead of recomputing for \$48 damage. The habit to break is answering from memory when the numbers changed.

The whole point in one line. The model did not improve between $4b$ and $4d$. The hold lowered the damage, the bar dropped from 86% to 50%, and the same 82% model went from unshippable to shippable.
